Updating DeskPRO

This article explains the three methods to update your DeskPRO Download v4 installation to the latest build.

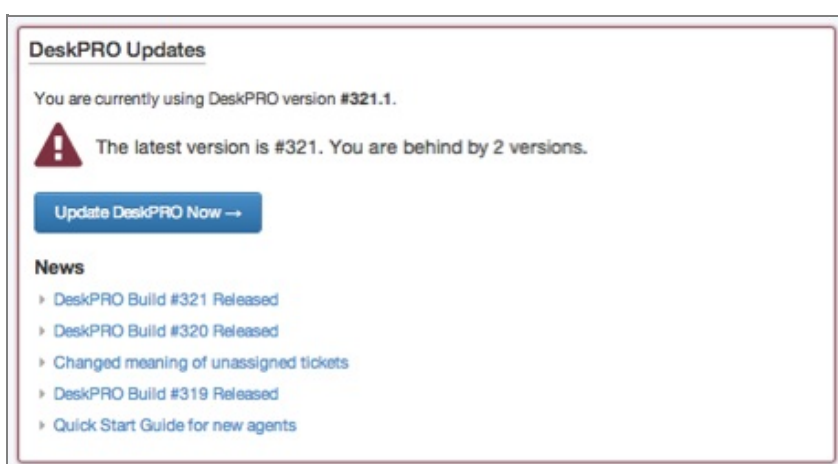

Note that if you have a DeskPRO Cloud account, we will automatically update your helpdesk for you. It usually takes a few days for the latest build to roll out.

If have a very old Download installation (v3 or earlier; i.e. you haven't updated for several years), see [Upgrading from old versions of DeskPRO](#) on our Knowledgebase.

Automatic update method

DeskPRO Download includes an automatic update tool in the Admin interface. For most configurations, this is the best method to use.

Just log in to the admin interface on your helpdesk, and at the upper left you will see a section listing the latest version, your version, and a button to update if you are outdated. Simply click the button to start the automatic update.

Prerequisites:

- The automatic update runs from the command-line through the scheduled task/cron system. This means that the user which runs the scheduled task must also be able to write all DeskPRO files. If there is a problem with permissions you will be notified during the process.

The update should usually only take a few minutes (possibly longer if you haven't updated for a long time).

If the upgrade 'sticks' on a particular step, go back to the admin interface. Examine the upgrade-util.log in the data folder of DeskPRO for any error messages.

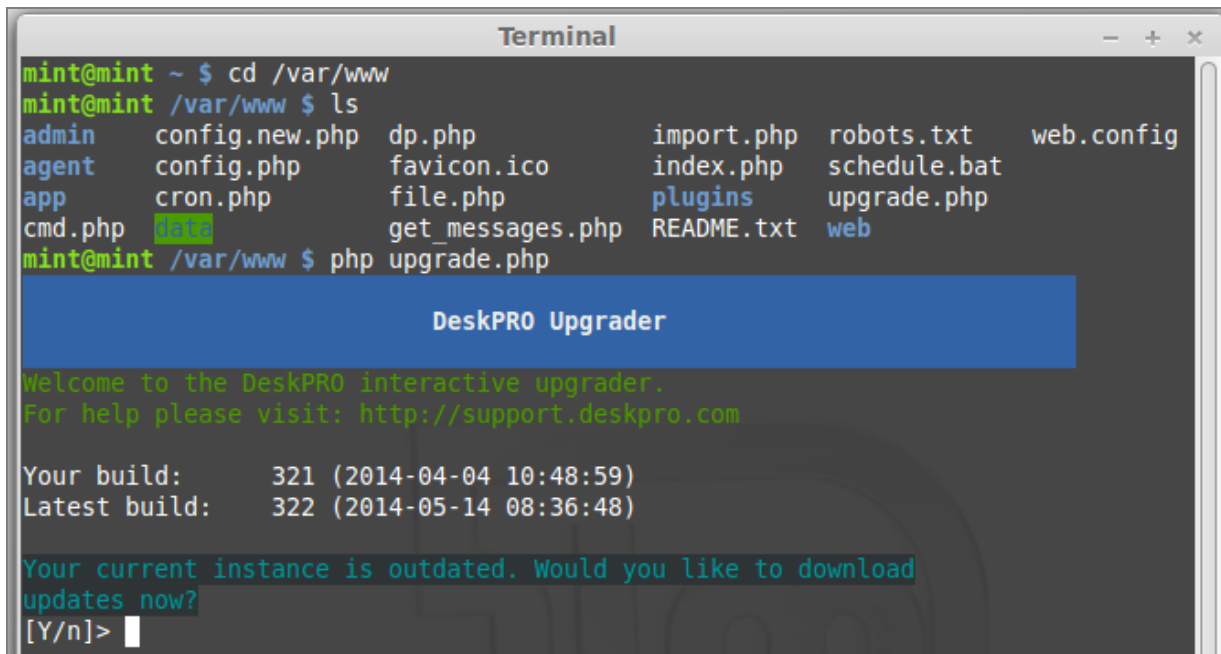

Interactive command-line method

You can also use the command-line upgrade utility to download and install updates.

If you are having problems with the automatic method, try using this, and send us any error messages.

This option works even if you have scheduled tasks/cron jobs disabled.

```
cd /path/to/deskpro php upgrade.php
```

The screenshot shows a terminal window titled "Terminal" with a dark background. The user is in the directory `/var/www` and has run `ls`, listing files: `admin`, `agent`, `app`, `cmd.php`, `config.new.php`, `config.php`, `cron.php`, `data`, `dp.php`, `favicon.ico`, `file.php`, `get_messages.php`, `import.php`, `index.php`, `plugins`, `README.txt`, `robots.txt`, `schedule.bat`, `upgrade.php`, `web.config`, and `web`. The user has then run `php upgrade.php`. The terminal displays the "DeskPRO Upgrader" banner, a welcome message, and the help URL <http://support.deskpro.com>. It shows the current build (321) and the latest build (322). A message states: "Your current instance is outdated. Would you like to download updates now?" followed by a prompt `[Y/n]>` with a cursor.

Manually installing updates

In some rare cases (for example, a failed update with one of the other methods), you may need to carry out the update manually.

- 1 Download the latest version of DeskPRO from <https://www.deskpro.com/downloads/deskpro.zip>
- 2 Make a backup of the current DeskPRO files before you install updates, in case you need to revert.
- 3 Copy your data/ directory and config.php files to a temporary location. You **must** keep these safe to avoid data loss.
- 4 Extract the zip you just downloaded and upload all files to your server. Overwrite/replace the existing files.
- 5 With the new files in place, use the command-line to run the upgrade tool.

```
cd /path/to/deskpro php cmd.php dp:upgrade
```

The tool will ask if you want to produce a database backup before applying updates. We highly recommend you answer 'yes', in case you need to revert the upgrade.

If your DeskPRO installation uses multiple webserver, you will need to update each one separately.
- 6 Copy the contents of the data/ directory that was created during the update process - it contains logs that may be important for troubleshooting.
- 7 Overwrite the data/ directory and config.php files with the original versions you copied in step 3.
